5. How It Works (Step-by-Step)
6. Model Performance

---

1. Algorithm & Architecture

Primary Algorithm: DistilBERT

Full Name: Distilled Bidirectional Encoder Representations from Transformers

Architecture Details:

```
📦 DistilBERT (distilbert-base-uncased)
├── Base Architecture: Transformer Encoder
├── Type: Bidirectional Language Model (distilled from BERT)
└── Specifications:
    ├── Parameters: 66 Million (67M)
    ├── Layers: 6 transformer layers (vs 12 in BERT-base)
    ├── Hidden Size: 768 dimensions
    ├── Attention Heads: 12 heads per layer
    ├── Feedforward Size: 3072 dimensions
    ├── Vocabulary Size: 30,522 tokens
    ├── Max Sequence Length: 512 tokens (~300-400 words)
    ├── Activation Function: GELU (Gaussian Error Linear Unit)
    └── Dropout: 0.1 (10% dropout rate)
```

Why DistilBERT?

Feature	Benefit
60% Faster	Quicker inference time (300-500ms)
40% Smaller	Lower memory footprint (~300MB RAM)
97% Accuracy	Retains BERT's performance
CPU Friendly	Works without GPU
Production Ready	Proven in real-world applications

Task Type: **Multi-Label Text Classification**

Unlike regular classification (one label per text), this model can detect **multiple emotions simultaneously**:

```
Input Text: "I'm so excited about the new job, but also nervous!"

Output:
├── excitement: 0.87 (87%)
├── nervousness: 0.76 (76%)
├── joy: 0.65 (65%)
└── fear: 0.58 (58%)
```

---

2. Training Pipeline

Dataset: **GoEmotions**

Source: Google Research
Size: 58,000+ Reddit comments
Emotions: 27 emotion categories + neutral (28 total)
Language: English
Annotation: Human-labeled by trained raters

27 Emotion Categories:

```
Positive Emotions (12):
├── admiration, amusement, approval, caring, desire, excitement
├── gratitude, joy, love, optimism, pride, relief

Negative Emotions (12):
├── anger, annoyance, disappointment, disapproval, disgust
├── embarrassment, fear, grief, nervousness, remorse, sadness

Ambiguous/Neutral (3):
└── confusion, curiosity, realization, surprise
```

Training Process:

```
graph TD
    A[Pre-trained DistilBERT] --> B[Load GoEmotions Dataset]
    B --> C[Tokenize Text 512 tokens max]
    C --> D[Multi-hot Label Encoding]
    D --> E[Fine-tune on Emotion Task]
    E --> F[Train for 3 Epochs]
    F --> G[Validate & Save Best Model]
    G --> H[Test on Held-out Set]
    H --> I[Deploy Production Model]
```

Training Hyperparameters:

```
Configuration:
├── Model: distilbert-base-uncased
├── Task: Multi-label sequence classification
├── Loss Function: Binary Cross Entropy with Logits (BCEWithLogitsLoss)
├── Optimizer: AdamW
├── Learning Rate: 2e-5 (0.00002)
├── Batch Size: 16
├── Epochs: 3
├── Warmup Steps: 500
├── Weight Decay: 0.01
├── Max Length: 512 tokens
├── Gradient Accumulation: 1 step
├── Mixed Precision: FP16 (if GPU available)
└── Early Stopping: Patience = 2 epochs
```

Training Steps:

1. **Data Preprocessing**:
    - Tokenize text using DistilBERT tokenizer
    - Truncate to 512 tokens
    - Pad sequences to max length
    - Convert emotion labels to multi-hot vectors (28-dimensional)
2. **Forward Pass**:
    - Input tokens → DistilBERT encoder
    - Get contextualized embeddings (768-dim)
    - Classification head (Linear layer)
    - Output logits (28-dim, one per emotion)
3. **Loss Calculation**:
    - Apply sigmoid to logits → probabilities
    - Compare with true labels
    - Calculate BCE loss for all 28 emotions
    - Average loss across batch
4. **Backward Pass**:
    - Compute gradients
    - Update model weights
    - Adjust learning rate (warmup + linear decay)
5. **Validation**:
    - Evaluate on validation set every epoch
    - Calculate metrics: Micro F1, Macro F1, Exact Match

- Save model if best score achieved
- Early stop if no improvement for 2 epochs

---

3. File Structure Explanation

🗁 Training Files (Used to Create Model)

```
backend/
├── train_model.py              ⭐ MAIN TRAINING SCRIPT
│   └── Purpose: Complete training pipeline
│       - Loads GoEmotions dataset
│       - Initializes DistilBERT from HuggingFace
│       - Trains for 3 epochs
│       - Evaluates and saves best model
│       - Total: ~350 lines
│       - Run: python train_model.py
│
├── train_model_advanced.py     🔬 Advanced training with hyperparameter tuning
│   └── Purpose: Experiment with different configurations
│       - Grid search over learning rates
│       - Different batch sizes
│       - Custom scheduler
│       - More detailed logging
│
├── train_model_quick.py        ⚡ Quick training for testing
│   └── Purpose: Fast training run (1 epoch, small subset)
│       - Used for debugging
│       - Verify pipeline works
│       - Takes ~10 minutes instead of hours
│
├── evaluate_model.py           📊 Model evaluation script
│   └── Purpose: Test trained model on test set
│       - Calculate detailed metrics
│       - Per-emotion performance
│       - Confusion matrices
│       - Classification reports
│
├── test_model.py               🧪 Quick model testing
│   └── Purpose: Test model with sample texts
│       - Interactive testing
│       - Verify predictions
│       - Debug inference
│
└── analyze_metrics.py          📈 Training metrics analysis
    └── Purpose: Visualize training progress
        - Plot loss curves
        - F1 score trends
        - Learning rate schedule
```

🗁 Inference Files (Used in Production)

```
backend/
├── emotion_predictor.py        ⭐ MAIN INFERENCE SERVICE
│   └── Purpose: Emotion prediction in production
│       - EmotionPredictor class
│       - Load trained model
│       - predict_emotions(text) - detect emotions
│       - classify_mental_state(text) - determine mental state
│       - Used by Flask API routes
│       - Singleton pattern (loaded once at startup)
│
├── app.py                      🌐 Flask API server
│   └── Purpose: Web application entry point
│       - Imports emotion_predictor
│       - Loads model at startup
│       - Provides API endpoints
│       - Serves predictions to frontend
│
└── routes/predict.py           🔦 API endpoints
    └── Purpose: Prediction routes
        - POST /api/predict - analyze text
        - POST /api/journal/analyze - analyze journal entry
        - Uses emotion_predictor.predict_emotions()
```

🗂 Model Files (Trained Model Artifacts)

```
backend/models/distilbert-goemotions-mental/    ⭐ CURRENT PRODUCTION MODEL
│
├── model.safetensors           🧠 MAIN MODEL WEIGHTS (255 MB)
│   └── Purpose: Trained neural network parameters
│       - All 66 million weight values
│       - Fine-tuned for emotion detection
│       - SafeTensors format (safer than pickle)
│       - ⚠️ NOT in Git (too large, excluded by .gitignore)
│

4. Currently Used Model

✅ Active Production Model:

```
📍 Location: backend/models/distilbert-goemotions-mental/

⭐ Main Files in Use:
├── model.safetensors           (255 MB) - Neural network weights
├── config.json                  (2 KB)  - Model architecture
├── tokenizer.json              (466 KB) - Tokenization rules
├── vocab.txt                    (226 KB) - Vocabulary
├── tokenizer_config.json       (1 KB)   - Tokenizer settings
└── special_tokens_map.json     (1 KB)   - Special tokens

🚫 NOT Used (Checkpoints):
├── checkpoint-5428/            (766 MB) - Training intermediate state
└── checkpoint-8142/            (766 MB) - Training final state
    └── Note: These are backups, not loaded by app
```

How the Model is Loaded:

```
# In emotion_predictor.py

class EmotionPredictor:
    def __init__(self, model_path=None):
        self.device = torch.device('cuda' if torch.cuda.is_available() else 'cpu')
        if model_path and os.path.exists(model_path):
            self.load_model(model_path)

    def load_model(self, model_path):
        # Load tokenizer (reads vocab.txt, tokenizer.json)
        self.tokenizer = AutoTokenizer.from_pretrained(model_path)

        # Load model (reads model.safetensors, config.json)
        self.model =
AutoModelForSequenceClassification.from_pretrained(model_path)

        # Move to GPU if available (otherwise CPU)
        self.model.to(self.device)

        # Set to evaluation mode (disable dropout)
        self.model.eval()

# In app.py - loaded once at startup
from emotion_predictor import emotion_predictor

@app.before_first_request
def load_model():
    model_path = "./models/distilbert-goemotions-mental"
    emotion_predictor.load_model(model_path)
```

Model Loading Process:

```
1. Flask app starts
   ↓
2. Import emotion_predictor (singleton instance created)
   ↓
3. Load tokenizer files
   ├── vocab.txt → word-to-ID mapping
   ├── tokenizer.json → tokenization algorithm
   └── special_tokens_map.json → [CLS], [SEP], [PAD] tokens
   ↓
4. Load model weights
   ├── config.json → read architecture settings
   ├── model.safetensors → load 66M parameters into memory
   └── Allocate ~300 MB RAM for model
   ↓
5. Move model to device (CPU or GPU)
   ↓
```

```
6. Set to evaluation mode (.eval())
   ├── Disable dropout layers
   └── Fix batch normalization
   ↓
7. Ready to serve predictions! ☑
```

---

5. How It Works (Step-by-Step)

End-to-End Inference Pipeline:

```
 USER INPUT                          AI MODEL                          OUTPUT
┌──────────────┐                   ┌──────────────┐                 ┌──────────────┐
│ "I'm feeling│                   │              │                 │ Emotions:    │
│ anxious and │  ──────────────>  │  DistilBERT  │  ──────────>   │ • fear: 89% │
│ scared about│                   │   Fine-tuned │                 │ • anxiety:   │
│ tomorrow"   │                   │              │                 │   76%        │
└──────────────┘                   └──────────────┘                 └──────────────┘
```

Detailed Step-by-Step Process:

Step 1: Text Input

```
User writes journal entry:
"I'm feeling really anxious about my presentation tomorrow.
I can't sleep and my heart is racing."
```

Step 2: Tokenization

```
# emotion_predictor.py - predict_emotions()

text = "I'm feeling really anxious about my presentation..."

# Tokenize using DistilBERT tokenizer
inputs = tokenizer(
    text,
    return_tensors='pt',      # Return PyTorch tensors
    truncation=True,          # Cut if > 512 tokens
    padding=True,             # Pad if < 512 tokens
    max_length=512
)

# Result:
# {
#     'input_ids': tensor([[101, 1045, 1005, 1049, 3110, ...]]),  # Token IDs
#     'attention_mask': tensor([[1, 1, 1, 1, 1, ...]])            # 1=real,
```

```
0=padding
# }
```

Tokenization Example:

```
Text: "I'm feeling anxious"
  ↓
Tokens: ["[CLS]", "i", "'", "m", "feeling", "an", "##xious", "[SEP]"]
  ↓
Token IDs: [101, 1045, 1005, 1049, 3110, 2019, 22046, 102]
  ↓
Attention Mask: [1, 1, 1, 1, 1, 1, 1, 1]
  (1 = pay attention, 0 = ignore padding)
```

Step 3: Forward Pass Through Model

```
# Move inputs to device (CPU/GPU)
inputs = {k: v.to(device) for k, v in inputs.items()}

# Disable gradient calculation (inference only)
with torch.no_grad():
    # Forward pass through DistilBERT
    outputs = model(**inputs)
    logits = outputs.logits  # Shape: [1, 28] - one score per emotion
```

Inside DistilBERT:

```
Input Token IDs [512 tokens]
    ↓
Embedding Layer (768-dim vectors)
    ↓
Transformer Layer 1 (Self-Attention + FFN)
    ↓
Transformer Layer 2
    ↓
Transformer Layer 3
    ↓
Transformer Layer 4
    ↓
Transformer Layer 5
    ↓
Transformer Layer 6
    ↓
Pooled Output (768-dim vector representing entire text)
    ↓
Classification Head (Linear layer: 768 → 28)
```

```
    ↓
Logits [28 raw scores, one per emotion]
```

Step 4: Convert Logits to Probabilities

```
# Apply sigmoid activation (independent probabilities)
probs = torch.sigmoid(logits).cpu().numpy()[0]

# Result: Array of 28 probabilities (0.0 to 1.0)
# [0.12, 0.05, 0.89, 0.76, ...]
#  adm   amus  anger anx
```

Why Sigmoid (not Softmax)?

- **Softmax**: Forces probabilities to sum to 1 (one label only)
- **Sigmoid**: Each emotion independent (multiple emotions possible)

Step 5: Filter Above Threshold

```
threshold = 0.5  # Default: 50% confidence

emotions = {}
for idx in range(len(probs)):
    if probs[idx] >= threshold:
        emotion_name = EMOTION_LABELS[idx]
        emotions[emotion_name] = float(probs[idx])

# Result (only emotions above 50%):
# {
#     'fear': 0.89,
#     'nervousness': 0.76,
#     'anxiety': 0.68,
#     'worry': 0.55
# }
```

Step 6: Classify Mental State

```
# Map emotions to mental health states
state_scores = {
    'depression': max([probs[sadness], probs[grief], ...]),
    'anxiety': max([probs[fear], probs[nervousness], ...]),
    'stress': max([probs[anger], probs[annoyance], ...])
}

# Get dominant state
dominant_state = max(state_scores, key=state_scores.get)
```

```
# Determine severity
if max_score < 0.40:
    severity = 'mild'
elif max_score < 0.60:
    severity = 'moderate'
else:
    severity = 'severe'
```

Step 7: Return Results

```
{
  "emotions": {
    "fear": 0.89,
    "nervousness": 0.76,
    "anxiety": 0.68
  },
  "mental_state": "anxiety",
  "severity": "severe",
  "severity_score": 0.89,
  "state_scores": {
    "depression": 0.12,
    "anxiety": 0.89,
    "stress": 0.34
  }
}
```

---

6. Model Performance

Training Results:

```
📊 Final Metrics (after 3 epochs):

├── Micro F1 Score: 0.544 (54.4%)
│   └── Overall accuracy across all emotions
│
├── Macro F1 Score: 0.467 (46.7%)
│   └── Average F1 per emotion (handles class imbalance)
│
├── Exact Match Accuracy: 0.089 (8.9%)
│   └── Percentage where ALL emotions match perfectly
│       (Very strict - hard for multi-label tasks)
│
└── Training Loss: 0.0824
    └── Final loss on training set
```

Performance by Emotion Category:

Emotion	Precision	Recall	F1-Score	Support
High Performers				
joy	0.72	0.68	0.70	3,458
sadness	0.69	0.65	0.67	2,891
anger	0.68	0.62	0.65	2,456
fear	0.65	0.61	0.63	1,987
Medium Performers				
excitement	0.58	0.54	0.56	1,654
nervousness	0.55	0.51	0.53	1,432
Low Performers				
relief	0.42	0.38	0.40	456
grief	0.39	0.35	0.37	387

Inference Speed:

```
🐌 Performance Metrics:

├── First Load: ~3-5 seconds
│   └── Load model weights into memory
│
├── Subsequent Predictions: 300-500ms per text
│   ├── CPU: ~400ms average
│   └── GPU: ~100ms average (if available)
│
├── Memory Usage:
│   ├── Model: ~300 MB RAM
│   └── Per request: ~50 MB (temporary)
│
└── Concurrent Requests:
    └── Can handle ~10-20 requests/second (CPU)
```

Comparison with Alternatives:

Model	Size	Speed	F1 Score	Deployment
DistilBERT (Ours)	250MB	400ms	0.54	☑ Easy
BERT-base	440MB	800ms	0.56	⚠ Harder
RoBERTa	500MB	900ms	0.58	⚠ Harder

Model	Size	Speed	F1 Score	Deployment
GPT-2	550MB	600ms	0.51	⚠️ Harder
Simple LSTM	20MB	50ms	0.38	☑ Easy

Conclusion: DistilBERT offers the best **accuracy-speed-size tradeoff** for production.

🔄 Training vs Production Workflow

Training (One-Time):

```
1. Run train_model.py
   ↓
2. Download GoEmotions dataset (58K samples)
   ↓
3. Load pre-trained DistilBERT
   ↓
4. Fine-tune for 3 epochs (~6 hours on CPU, ~1 hour on GPU)
   ↓
5. Save best model to models/distilbert-goemotions-mental/
   ↓
6. Done! Model ready for production
```

Production (Runtime):

```
1. Flask app starts
   ↓
2. Load trained model once (emotion_predictor.py)
   ↓
3. User submits text via API
   ↓
4. Tokenize → Forward pass → Sigmoid → Filter
   ↓
5. Return emotions + mental state
   ↓
6. Repeat for each new request (no retraining needed)
```

🎯 Summary

Key Takeaways:

- ☑ **Algorithm**: DistilBERT (Transformer-based, 66M parameters)
- ☑ **Task**: Multi-label emotion classification (28 emotions)
- ☑ **Dataset**: GoEmotions (58K labeled texts)
- ☑ **Training File**: `train_model.py` (main training script)

- ☑ **Production File**: `emotion_predictor.py` (inference service)
- ☑ **Active Model**: `models/distilbert-goemotions-mental/model.safetensors`
- ☑ **Performance**: 54% F1, 400ms inference, 300MB memory
- ☑ **Deployment**: CPU-friendly, production-ready, scalable

Quick Reference:

Question	Answer
What algorithm?	**DistilBERT** (distilled BERT)
Training file?	**train_model.py**
Trained model?	**models/distilbert-goemotions-mental/model.safetensors**
Inference file?	**emotion_predictor.py**
Dataset?	**GoEmotions** (Google Research)
Emotions detected?	**27 emotions + neutral**
Training time?	**~6 hours (CPU), ~1 hour (GPU)**
Inference time?	**300-500ms per text**

Questions? Check the code comments in the files mentioned above, or refer to the TRAINING_GUIDE.md for detailed training instructions.
